

Presentation Skills & Technical Seminar Project Abstract

Topic: Behavior-Based Phishing Attack Detection Using Artificial Intelligence

Phishing attacks continue to be a serious cyber security threat, targeting users by imitating legitimate websites to steal sensitive information such as login credentials and financial details. Conventional phishing detection techniques mainly depend on blacklists and static rules, which are ineffective against newly created and rapidly evolving phishing websites. To address this limitation, behavior-based phishing detection using Artificial Intelligence (AI) has emerged as an effective and adaptive solution.

My project focuses on identifying phishing attacks by analyzing behavioral characteristics of websites rather than relying only on known signatures. AI and machine learning models examine features such as abnormal URL structures, redirection patterns, webpage layout inconsistencies, suspicious login forms, and user interaction behavior. By learning these patterns, the system can accurately differentiate between legitimate and phishing websites, including previously unseen attacks. The seminar discusses the working approach, advantages, and real-world applications of behavior-based phishing detection systems in browsers, email platforms, and enterprise security solutions.
